

Greenplum Healthcheck Deployment Guide

It is strongly recommended to run the Greenplum Healthcheck script in a **restrictive mode** and **during off-peak hours**. This scheduling is important because certain internal operations, such as `gpcheckcat` and functions like `gp_size_of_table_disk`, can significantly increase execution time, especially in a production environment.

Prerequisites

Before execution, have the following information readily available:

- The Greenplum Port Number.
- The full file path to the GP Hosts file.

Execution Instructions

Perform the following steps on your Greenplum coordination host:

1. **Extract:** Unzip the GP health check script into the `/home/gpadmin/` directory.
2. **Log In:** Access your Greenplum environment using the `gpadmin` user.
3. **Set Permissions:** Grant execute permission to the script using the command: `chmod +x gp_healthcheck_html_v1.sh`.
4. **Run:** Execute the script: `gp_healthcheck_html_v1.sh`. The process will generate a log file named `<Company name>_gp_healthcheck_report_<timestamp>.html` upon completion.
5. **Review and Submit:** Before sending the report to the Tanzu account team, inspect the generated HTML file for any confidential information.
6. **Share:** Send the reviewed report file to the Tanzu account team for their assessment.
